

WARP RIFLE

Description

Antimatter combines with Fuse at the point of impact, forming a small, contained rift in spacetime. These merging substances accumulate with each shot, destabilizing the surrounding molecules and increasing the potential of forming a volatile singularity that devours the target. The resulting gravitational shockwave knocks back nearby targets and increases the volatility of the remaining antimatter on the battlefield.

History

The Warp Rifle began as a project solely intended to stabilize the containment of antimatter. However, as the C.I.A.'s understanding of Fuse grew, they instructed Hyperion personnel to explore military applications for every Xenotech prototype they engineered. Therefore, antimatter containment became secondary and its reaction to Fuse became the central focus, turning this containment project into a devastatingly-efficient tactical weapon.

MAGSHIELD

Description

Utilizing a heavily-augmented ferrofluid combined with Fuse, this Xenotech weapon triggers a low-voltage microwave signal to create a thin, magnetized membrane barrier. Projectiles fired from behind the user rip through the substance untouched, however incoming projectiles force the barrier to seize up instantly, trapping projectiles on the surface and shielding the user from harm. A secondary trigger allows the user to momentarily increase the voltage of the microwave signal, which causes an instant reverse in polarity. This forces all trapped projectiles on the surface of the shield to rapidly repel outward in a torrent of excess Fuse.

History

The Mag Shield was conceived as a portable shield for riot troops entering urban combat zones. Originally considered a solely defensive gadget, a deadly electrical experiment gave birth to its assault functionality. Normally, the test device required a constant low-voltage electrical current for the shield to remain stable. When the voltage was increased in an attempt to grow the shield's effective surface area, a rapid, polarity-inverting magnetic vibration erupted from it. Tragically, the torrent of Fuse that the shield exhausted during the inversion of polarity vaporized all organic matter in close proximity. While this was considered a dark day for the lives lost at the Hyperion facility, the C.I.A.'s funding contract was quietly updated requiring this bug to be included as a feature.

ARCSHOT

Description

Firing mercury-tipped bolts, this Xenotech weapon applies Fuse to each shot as it leaves the stock. The reaction of Fuse making contact with the mercury tip heats the projectile to 1300 Kelvin, which not only perforates organic targets but also drives into most solid materials. This facilitates not only long-range deadly precision, but also the ability to 'pin' a target to the wall. By upgrading this weapon with a remote-activation switch, the user can ignite the heated mixture on the bolt's tip, causing the projectile to emit Fuse-augmented mercury tendrils that whip and lacerate anyone within close proximity.

History

After some success at momentary stabilization of Fuse, the first clinical tests administered were direct cause-and-effect trials of the substance with every element on the periodic table. Mercury (Hg 80) was a proven reactant whose effects were considered stable enough for weaponization. However, initial ballistic tests were complete failures. The scientists struggled to find a way to keep the Fuse from heating the mercury before firing, forcing the project to be shelved for nearly a decade. The project was reopened after one scientist had an especially vivid dream of hunting on safari with his wife. He ran into the testing chamber, proudly recounted his dream, and presented the idea of trying a crossbow with mercury-tipped bolts and applying Fuse at point of release. This revelation kept the weapon cool enough for use by having the reaction occur in mid-air.

SHATTERGUN

Description

Dual-chambered glass rounds containing compressed melanite and Fuse are fired at high velocity creating a violent molecular reaction at point of contact with the target. When the round shatters, the Fuse reacts with the melanite and rapidly duplicates the augmented substance, encasing the target in living crystal. Immobilization persists until the crystal's molecular structure erodes a short time later.
